

Incident Title		Batch Reactor Internal Overpressure	
Incident Type		Runaway Reaction	
Date		28 th April 2008	
Country		Ireland	
Location		Cork (Munster)	
Fatalities		Injuries	Cost
1		1	Unknown
Incident Description		<p>The active drug intermediate compound 2-cyano-3-methylpyridine (CMP) was being manufactured by batch reaction of picoline-N-oxide (PNO) with diethylcarbamoyl chloride (DECC) in acetone (C₃H₆O). The resultant intermediate, an acyloxy pyridinium salt, is then further reacted with an aqueous solution of sodium cyanide (NaCN) in another reactor to produce the CMP product. On the day of the day of the incident, a glass-lined, mechanically agitated carbon steel reactor suffered significant deformation and a blowout of the manway gasket and solids addition (charge) chute top cover, resulting in the release of reactants at high temperature and pressure. Two operators were present at the time. Both were severely injured (one later died from his injuries). The reactor and associated hardware suffered significant damage. The blast wave from the vessel failure also caused extensive damage to the 4-storey building.</p>	
			
Incident Analysis		<p>Basic cause was failure of the reactor manway gasket and loss of primary containment (LOPC) due to an exothermic runaway chemical reaction and consequent two-stage thermal decomposition (acyloxy pyridinium salt and then picoline-N-oxide) when the exothermic onset temperature was reached.</p> <p>Critical factors included: 1) PNO and acyloxy pyridinium salts are thermally unstable and decompose violently, 2) The acetone solvent charge step prior to DECC addition was omitted (reason unknown), 3) Omission of acetone solvent results in a lower acyloxy pyridinium salt decomposition onset temperature and a more violent decomposition reaction, 4) Omission of acetone solvent also increases the reaction mix batch viscosity, adversely affecting mixing and heat transfer efficiency, 5) The consequences of omitting acetone solvent addition were underestimated in the HAZOP review, 6) The solids charge chute provided (unintended) additional emergency relief capacity which may have prevented catastrophic failure of the reactor vessel.</p> <p>Root causes included: 1) Inadequate process hazard analysis (HAZOP) and risk assessment, 2) Inadequate operating procedures (addition of acetone not highlighted as safety-critical step), 3) Inadequate design (pressure safety valve (PSV) and bursting disc (BD) set pressures and relief line sizing), 4) Inadequate emergency procedures (operators required to approach unstable reactor to close valves to isolate reactor overheads glassware).</p>	
Lessons Learned		<p>1) Process hazard analysis (HAZOP) and risk assessment reviews should be carried out by experienced and competent staff with the full breadth of chemistry, process, engineering and operating knowledge,</p> <p>2) Quantitative reaction hazard assessment data (thermal stability tests, calorimetry, etc) must be used to inform design of appropriate safeguards,</p> <p>3) Operating procedures should clearly identify safety-critical steps,</p> <p>4) Reliance solely on plant operators to routinely carry out safety-critical tasks or to approach a reactor operating out of control is not acceptable.</p>
